First name: __________________________________________

Last name: __________________________________________

Matr. number: _______________________________________

Course of study (please mark exactly one):
○ Master of Informatik
○ Bachelor of Informatik – for Master’s studies

• On every sheet please give your first name, last name, and matriculation number.
• You must solve the exam without consulting any extra documents (e.g., course notes).
• Make sure your answers are readable. Do not use red pens or pencils.
• Please answer the exercises on the exercise sheets. If needed, also use the back sides of the exercise sheets.
• Answers on extra sheets can only be accepted if they are clearly marked with your name, your matriculation number, and the exercise number.
• Cross out text that should not be considered in the evaluation.
• Students that try to cheat do not pass the exam.
• At the end of the exam, please return all sheets together with the exercise sheets.

Grade -
Exercise 1 \((4 + 3 + 4 + 5 = 16\) points\)

The following data structure represents polymorphic lists that can contain values of two types in arbitrary order:

\[
\text{data DuoList a b = C a (DuoList a b) \mid D b (DuoList a b) \mid E}
\]

Consider the following list \(zs\) of integers and characters:

\[
[4, 'a', 'b', 6]
\]

The representation of \(zs\) as an object of type \text{DuoList Int Char} in Haskell would be:

\[
C 4 (D 'a' (D 'b' (C 6 E)))
\]

Implement the following functions in Haskell.

(a) The function \(\text{foldDuo}\) of type

\[
(a \rightarrow c \rightarrow c) \rightarrow (b \rightarrow c \rightarrow c) \rightarrow c \rightarrow \text{DuoList a b} \rightarrow c
\]

works as follows: \(\text{foldDuo f g h xs}\) replaces all occurrences of the constructor \(C\) in the list \(xs\) by \(f\), it replaces all occurrences of the constructor \(D\) in \(xs\) by \(g\), and it replaces all occurrences of the constructor \(E\) in \(xs\) by \(h\). So for the list \(zs\) above,

\[
\text{foldDuo} \ (\ast) \ (\\lambda x y \rightarrow y) \ 3 \ zs
\]

should compute

\[
(\ast) \ 4 \ ((\\lambda x y \rightarrow y) \ 'a' \ ((\\lambda x y \rightarrow y) \ 'b' \ ((\ast) \ 6 \ 3)))
\]

which in the end results in 72. Here, \(C\) is replaced by \((\ast)\), \(D\) is replaced by \((\\lambda x y \rightarrow y)\), and \(E\) is replaced by 3.
(b) Use the `foldDuo` function from (a) to implement the `cd` function which has the type
`DuoList Int a -> Int` and returns the sum of the *entries* under the data constructor C
and of the *number of elements* built with the data constructor D.

In our example above, the call `cd zs` should have the result 12. The reason is that `zs`
contains the entries 4 and 6 under the constructor C and it contains two elements ’a’ and
’b’ built with the data constructor D.
(c) Consider the following data type declaration for natural numbers:

\[
\text{data Nats = Zero} \mid \text{Succ Nats}
\]

A graphical representation of the first four levels of the domain for \textit{Nats} could look like this:

\[
\text{Succ (Succ Zero)} \quad \text{Succ (Succ (Succ \bot))}
\]

\[
\text{Succ Zero} \quad \text{Succ (Succ \bot)}
\]

\[
\text{Zero} \quad \text{Succ \bot}
\]

\[
\bot
\]

We define the following data type \textit{Single}, which has only one data constructor \textit{One}:

\[
\text{data Single = One}
\]

Sketch a graphical representation of the first three levels of the domain for the data type \textit{DuoList \textit{Bool Single}}.
(d) Write a Haskell function `printLength` that first reads a line from the user, then prints this string on the console and in the end also prints the length of this string on the console. Also give the type declaration for your function.

You may use the `do`-notation, but you are not obliged to use it. Some of the following pre-defined functions can be helpful:

- `getline :: IO String` reads a line from the user
- `length :: String -> Int` has the length of a string as its result
- `show :: Int -> String` converts a number to a string
- `putStr :: String -> IO ()` writes a string to the console

An example run should look as given below. Here the string “foo” was read from the user.

```
Main> printLength
foo
foo3
```
Exercise 2 (4 + 5 = 9 points)

Consider the following Haskell declarations for the square function:

\[
\text{square :: Int} \rightarrow \text{Int}
\]

\[
\text{square 0 } = 0
\]

\[
\text{square (x+1) } = 1 + 2x + \text{square x}
\]

(a) Please give the Haskell declarations for the higher-order function \textit{f} \textit{square} corresponding to \textit{square}, i.e., the higher-order function \textit{f} \textit{square} such that the least fixpoint of \textit{f} \textit{square} is \textit{square}. In addition to the function declaration(s), please also give the type declaration of \textit{f} \textit{square}. Since you may use full Haskell for \textit{f} \textit{square}, you do not need to translate \textit{square} into simple Haskell.

(b) We add the Haskell declaration \textit{bot} = bot. For each \( n \in \mathbb{N} \) please determine which function is computed by \textit{f} \textit{square} \textit{n} \textit{bot}. Here "\textit{f} \textit{square} \textit{n} \textit{bot}" represents the \( n \)-fold application of \textit{f} \textit{square} to \textit{bot}, i.e., it is short for \( \underbrace{\textit{f} \textit{square} (\textit{f} \textit{square} \ldots (\textit{f} \textit{square} \textit{bot}) \ldots)}_{n \text{ times}} \).

Let \( f_n : \mathbb{Z}_\perp \rightarrow \mathbb{Z}_\perp \) be the function that is computed by \textit{f} \textit{square} \textit{n} \textit{bot}.

Give \( f_n \) in \textbf{closed form}, i.e., using a non-recursive definition.
Exercise 3 (6 points)

Let $D_1, D_2$ be domains, let $\subseteq_{D_2}$ be a complete partial order on $D_2$. As we know from the lecture, then also $\subseteq_{D_1 \rightarrow D_2}$ is a complete partial order on the set of all functions from $D_1$ to $D_2$.

Prove that $\subseteq_{D_1 \rightarrow D_2}$ is also a complete partial order on the set of all constant functions from $D_1$ to $D_2$. A function $f : D_1 \rightarrow D_2$ is called constant iff $f(x) = f(y)$ holds for all $x, y \in D_1$.

Hint: The following lemma may be helpful:

If $S$ is a chain of functions from $D_1$ to $D_2$, then $\sqcup S$ is the function with:

$$(\sqcup S)(x) = \sqcup \{f(x) \mid f \in S\}$$
Exercise 4 (6 points)

We define the following data structures for natural numbers and polymorphic lists:

```haskell
data Nats = Zero | Succ Nats

data List a = Nil | Cons a (List a)
```

Consider the following expression in complex Haskell:

```haskell
let length Nil = Zero
    length (Cons x xs) = Succ (length xs)
in length
```

Please give an equivalent expression `let length = ... in length` in simple Haskell.

Your solution should use the functions defined in the transformation from the lecture such as `sel_n, isa_constr,` and `argof_constr`. However, you do not have to use the transformation rules from the lecture.
Exercise 5 (4 + 5 = 9 points)

Consider the following data structure for polymorphic lists:

\[
\text{data } \text{List } a = \text{Nil} \mid \text{Cons } a \ (\text{List } a)
\]

(a) Please translate the following Haskell-expression into an equivalent lambda term (e.g., using \textit{Lam}). Recall that pre-defined functions like \texttt{even} are translated into constants of the lambda calculus. It suffices to give the result of the transformation.

\[
\text{let } f = \lambda x \rightarrow \text{if } (\text{even } x) \text{ then Nil else Cons } x \ (f \ x) \\
\text{in } f
\]
(b) Let $\delta$ be the set of rules for evaluating the lambda terms resulting from Haskell, i.e., $\delta$ contains at least the following rules:

\[
\text{fix} \rightarrow \lambda f. f (\text{fix } f) \\
\text{plus } 2 \ 3 \rightarrow 5
\]

Now let the lambda term $t$ be defined as follows:

\[t = (\text{fix } (\lambda g. \text{Cons } (\text{plus } x 3) \text{ Nil})) \ 2\]

Please reduce the lambda term $t$ by WHNO-reduction with the $\rightarrow_{\beta\delta}$-relation. You have to give all intermediate steps until you reach weak head normal form (and no further steps).
Exercise 6 (10 points)

Use the type inference algorithm \( \mathcal{W} \) to determine the most general type of the following lambda term under the initial type assumption \( A_0 \). Show the results of all sub-computations and unifications, too. If the term is not well typed, show how and why the \( \mathcal{W} \)-algorithm detects this.

\[
\lambda f. \ (\text{Succ} \ (f \ x))
\]

The initial type assumption \( A_0 \) contains at least the following:

\[
\begin{align*}
A_0(\text{Succ}) & = \ (\text{Nats} \rightarrow \text{Nats}) \\
A_0(f) & = \ \forall a. \ a \\
A_0(x) & = \ \forall a. \ a
\end{align*}
\]
